***Interpretation of Exam Performed at Orthopedics and Sports Medicine of Oregon***

**MRI, RIGHT SHOULDER**

**History:** Pain, numbness, and weakness with external rotation and abduction. Prior arthroscopy, 2002 for rotator cuff tear.

**Comparison:** None.

**Procedure:** Sagittal and coronal T1 and STIR. Axial STIR.

**Findings:** There are mild degenerative changes of the AC joint with enthesophyte at the proximal attachment of the coracoacromial ligament. The humerus is high riding with some remodeling of the undersurface of the distal acromion. There are mild degenerative changes of the glenohumeral joint.

There is extensive full-thickness cuff tear of the distal supraspinatus and infraspinatus with proximal retraction and muscle atrophy. The subscapularis appears intact. The proximal intraarticular portion of the biceps tendon appears intact. It is not well seen in its distal intraarticular location but is seen to be intact more distally in the bicipital groove. Some deformity of the greater tuberosity may be related to prior cuff tear and surgical repair with small depressions and marginal sclerosis.

**IMPRESSION**

Chronic extensive rotator cuff tear of the supraspinatus and infraspinatus with degenerative change and high-riding humeral head.
